## Fixed and Demand-Oblivious Topology

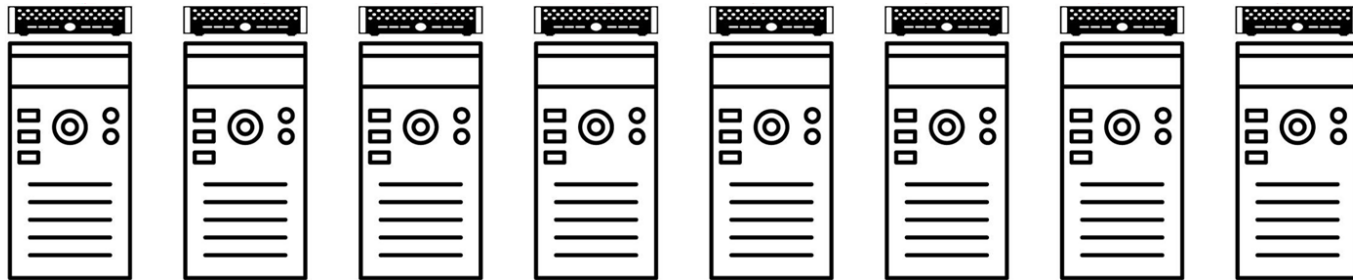

Highway which ignores  
actual traffic:  
**frustrating!**

Many flavors,  
but in common:  
fixed and  
**oblivious** to  
actual demand.

→ Optical Circuit Switch rapid adaption of physical layer  
→ based on rotating mirrors

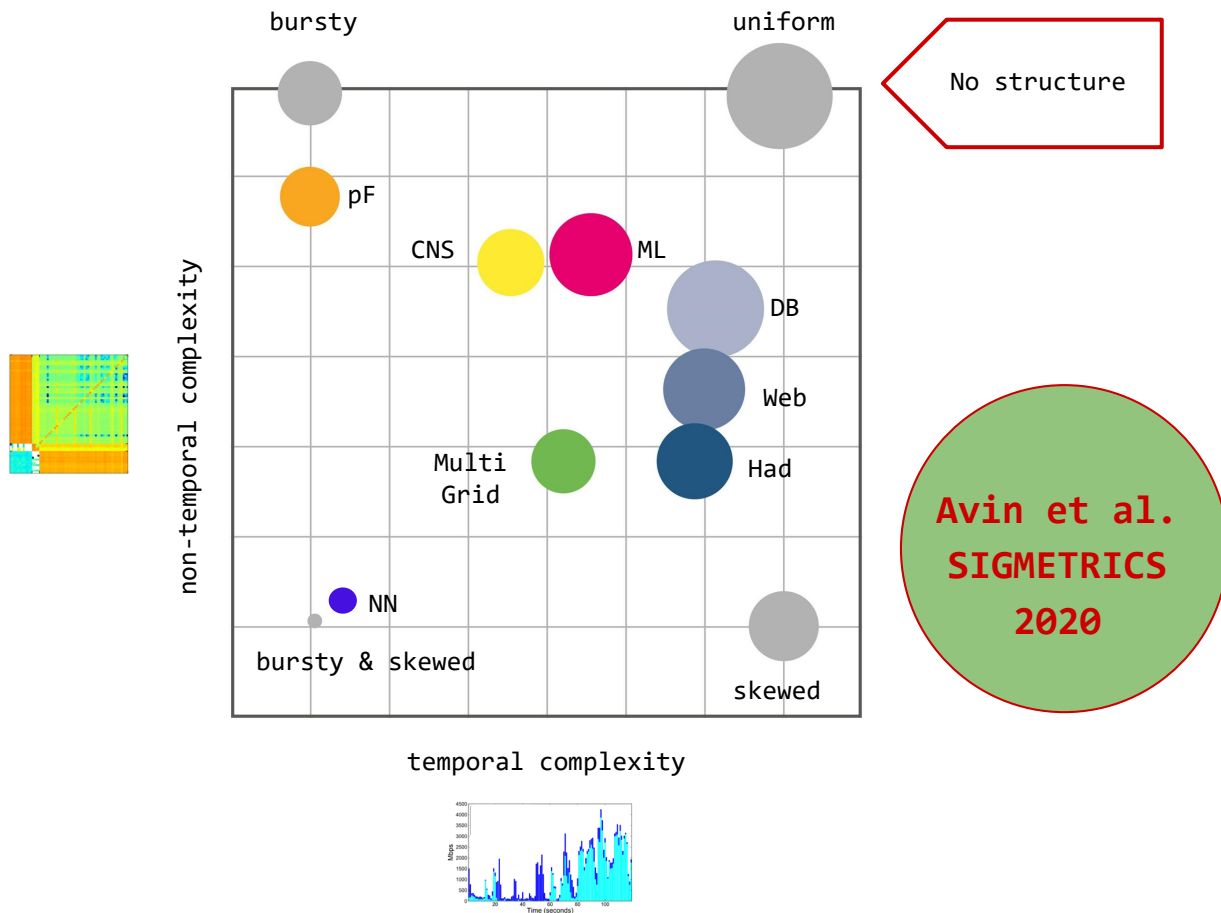

Optical Circuit Switch

By Nathan Farrington, SIGCOMM 2010

# Empirical Motivation

## Temporal and Spatial Structure

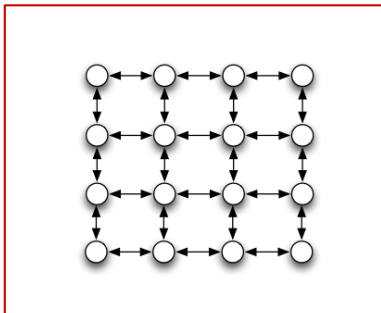

Source: Avin et al., On the Complexity of Traffic Traces and Implications, SIGMETRICS 2020

# The Potential

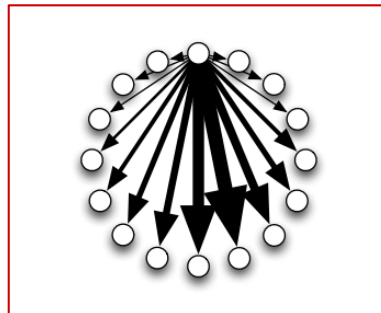

## Example: Expected Route Length

- **Expected path length**: number of hops times demand
- Consider design of **constant degree** topologies (e.g., 4)
- Note: diameter is at least **logarithmic**

Demand 1: Low Degree

Demand 2: Skewed

Expected route length in demand-aware network is **constant** in these cases (while diameter is  $\Omega(\log n)$ ).

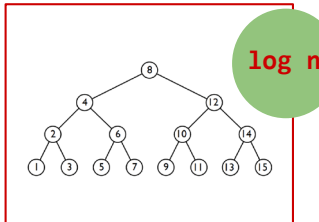

# Connection to Entropy

→ Achievable expected route length is proportional to **conditional entropy** of the demand matrix

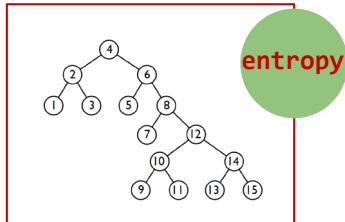

→ Similar to coding and data structures:

Avin et al.  
DISC 2017

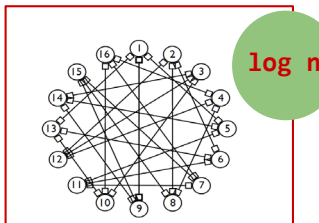

Traditional BST /  
worst-case coding

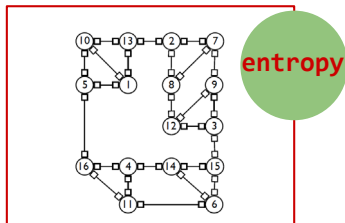

Demand-aware BST /  
Huffman coding

Traditional networks /  
worst-case traffic

Demand-aware BST /  
Huffman coding

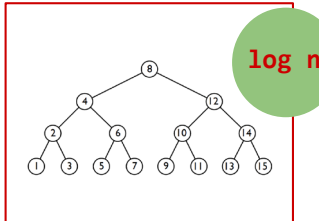

# Connection to Entropy

→ Achievable expected route length is proportional to **conditional entropy** of the demand matrix

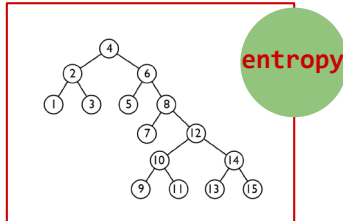

→ Similar to coding and data structures:

Avin et al.

Traditional BST /  
worst-case coding

 $\log n$ 

Demand-aware BST / Huffman coding

entropy

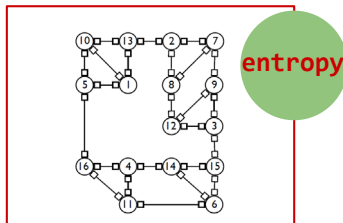

Traditional networks /  
worst-case traffic

$\log n$

Demand-aware BST / Huffman coding

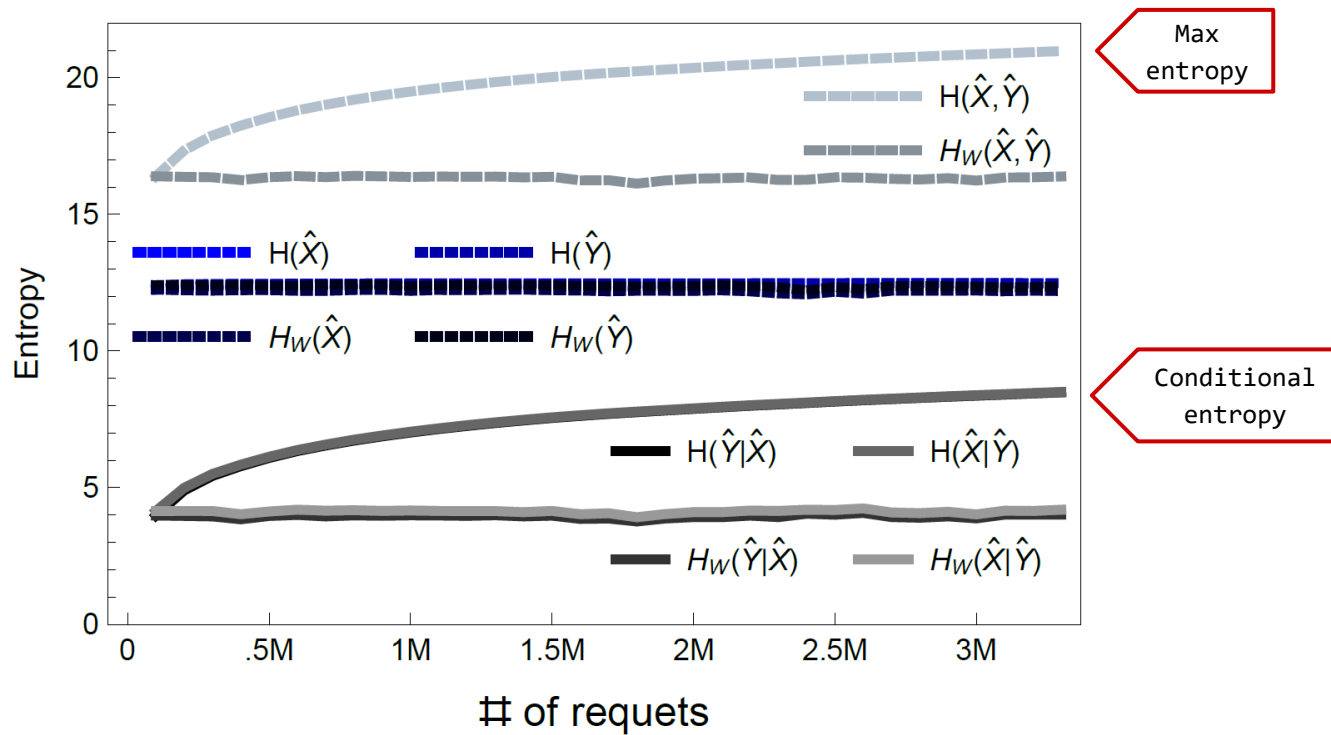

entropy

But how to achieve short routes if the demand is not known ahead of time and we have to account for reconfiguration costs?

# Example

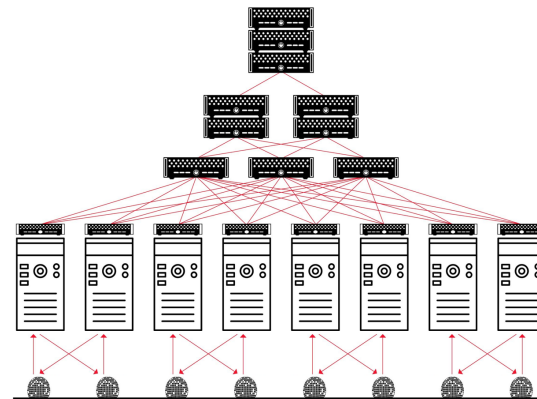

## Facebook's Datacenter Traces

# Our Contribution:

## ReNet, A Statically Optimal Demand-Aware Network

- Model: **hybrid architecture**
  - Fixed network of diameter  $\log n$  plus reconfigurable network (**constant** number of direct links)
  - **Segregated** routing
  - **Online** sequence of requests:  
 $\sigma = (\sigma_1, \sigma_2, \sigma_3, \dots)$
  - Global controller

fixed

reconfigurable

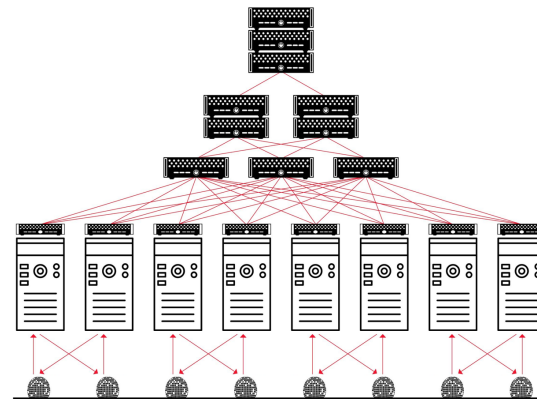

- **Objective:** Minimize route length plus reconfigurations
  - More specifically:  
be **statically optimal**
  - Compared to a fixed algorithm which knows  $\sigma$  ahead of time

# Our Contribution:

## ReNet, A Statically Optimal Demand-Aware Network

fixed

reconfigurable

- **Objective:** Minimize route length plus reconfigurations
  - More specifically:
    - be **statically optimal**
  - Compared to a fixed algorithm which knows  $\sigma$  ahead of time

- Compact routing (constant tables)
- Local routing (greedy)
- Arbitrary addressing

# The ReNet Algorithm (1)

Algorithmic building blocks:

1. **Working Set** (WS)

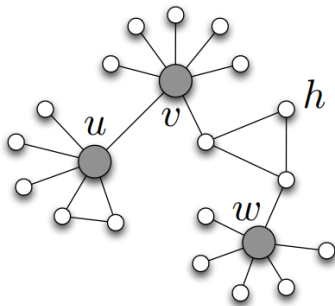

→ Nodes keep track of recent communication partners in  $\sigma$ .

2. Small/large nodes and **Ego-Tree**

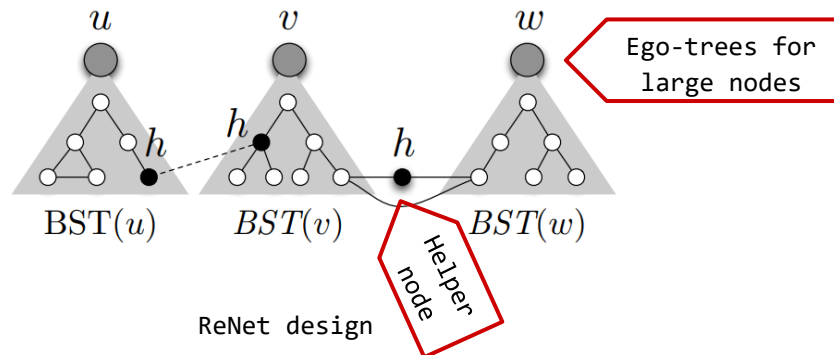

→ Nodes with small WS connect to WS directly, nodes with large WS via a self-adjusting binary search tree (e.g., a **splay tree**)

3. **Helper nodes** to reduce the degree

→ Large nodes may appear in many ego-trees, so get help of small nodes

Demand graph

ReNet design

# The ReNet Algorithm (2)

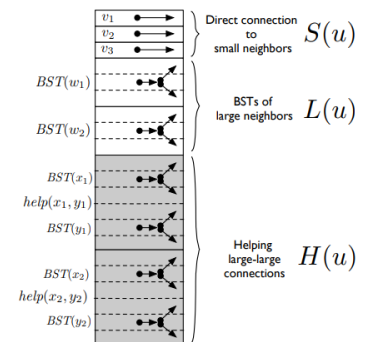

Continued:

## 4. Self adjustments

→ Keep track of WS; when too large: **flush-when-full**

## 5. Centralized coordination

- Fairly **decentralized**: coordinator only needs to keep track of which nodes are large and which small
- Nodes inform coordinator when adding node to working set
- Coordinator then assigns helper node on demand

# Analytical Results (1)

Theorem 1:

For any **sparse** communication sequence of a certain length, ReNets are statically optimal while ensuring a bounded degree.

- Sparse: subsequences of only involve a linear number of nodes
- Required to ensure availability of helper nodes (DISC 2017)

# Analytical Results (2)

Theorem 2:

Under certain communication patterns, the amortized cost of ReNet can be significantly lower than the static optimum, i.e.,  $\Omega(\log n)$ .

- Example: consider sequence of  $\sigma = (\sigma^{(1)}, \sigma^{(2)}, \sigma^{(3)}, \dots)$  where each  $\sigma^{(i)}$  is of length  $n \log n$ , sparse and corresponds to different **2-dimensional grid**.
- In this example, the cost of ReNet is **constant** for each  $\sigma^{(i)}$ .
- Overall, the union of the grids form a uniform pattern, so the cost of the static algorithm is  **$\log n$**  (for constant degree).

# Conclusion

- ReNet: statically optimal and
  - compact routing
  - local routing
  - arbitrary addressing
- Avenues for future work
  - dense communication
  - dynamic optimality

Thank you!

## AdjustNet

Breaking new ground with demand-aware self-adjusting networks

**Our Vision:**  
Flexible and Demand-Aware Topologies

The diagram illustrates a network topology with 8 nodes (labeled 1 to 8) and their connections. A green box highlights the 'Self-Adjusting Networks' concept. A red box indicates 'new demand' and another red box indicates 'new flexible interconnect'. A red box also indicates 'e.g., servers, cloud'.
